Background

- There is an increased interest in development and use of serum-derived biomarkers for monitoring of multiple sclerosis (MS).
- The ability to concurrently measure several biomarkers which represent multiple MSspecific pathophysiologic pathways using a multivariate proteomic panel could further improve the sensitivity and specificity relative to any of the biomarkers individually.

Objective

• To determine the predictivity of multivariate proteomic assay for concurrent and future microstructural axonal brain pathology in a heterogeneous group of persons with multiple sclerosis (pwMS).

Methods

- A proteomic analysis was obtained on serum samples from 202 persons with MS (148 relapsing-remitting pwMS and 54 progressive pwMS) at the baseline and 5-year follow-up.
- The concentration of 21 proteins related to multiple pathways of MS pathophysiology were derived using a custom assay panel validated for MS disease assessments. (Table 1)
- The severity of microstructural axonal brain pathology was quantified by a 3T MRI-based diffusion tensor imaging (DTI). Fractional anisotropy (FA) and mean diffusivity (MD) of normal-appearing brain tissue (NABT), normal-appearing white matter (NAWM), gray matter (GM), and T2 and T1 lesions were calculated.
- Age, sex and body -mass index-adjusted stepwise regression models were used.

Table 1. List of proteomic biomarkers analyzed using the multivariate assay.

| - | | | | | |
|-----------|---------------------------------------|--|--|--|--|
| Marker | Name (Alias) | | | | |
| NfL | Neurofilament Light | | | | |
| MOG | Myelin-oligodendrocyte glycoprotein | | | | |
| CD6 | Cluster of Differentiation 6 | | | | |
| CXCL13 | C-X-C Motif Chemokine Ligand 13, | | | | |
| | BLC | | | | |
| CXCL9 | CXCL9, Monokine Induced by | | | | |
| | Gamma Interferon, MIG | | | | |
| CDCP1 | CUB domain-containing protein 1 | | | | |
| CCL20 | MIP-3 alpha | | | | |
| OPG | Osteoprotegerin, TNFRSF11B | | | | |
| IL-12B | Interleukin 12B | | | | |
| APLP1 | Amyloid Beta Precursor Like Protein 1 | | | | |
| GH | Somatotropin, Growth Hormone | | | | |
| VCAN | Versican, versican proteoglycan | | | | |
| TNFRSF10A | TRAILR1, DR5 - Death Receptor 5 | | | | |
| COL4A1 | Collagen alpha-1 (IV) chain | | | | |
| SERPINA9 | Serpin family A member 9 | | | | |
| PRTG | Protogenin | | | | |
| FLRT2 | Fibronectin leucine-rich repeat | | | | |
| | transmembrane protein | | | | |
| TNFSF13B | BAFF | | | | |
| OPN | Osteopontin | | | | |
| CNTN2 | Contactin 2 | | | | |
| GFAP | Glial Fibrillary Acidic Protein | | | | |

Results

- Glial fibrilary acidic protein (GFAP) was the most common and highest ranked proteomic biomarker associated with greater concurrent microstructural CNS damage (p<0.001).
- Higher baseline GFAP levels were significant predictors of future wide-spread microstructural damage as measured by NABT FA and MD (standardized β=-0.397/0.327, p<0.001), NAWM FA (standardized β=-0.466, p<0.0012), GM MD (standardized β=0.346, p<0.011) and T2 lesions MD (standardized β=0.416,p<0.001) at the 5-year follow-up. (Table 2)
- Serum levels of MOG, NfL, contactin-2 and osteopontin proteins were additionally and independently associated with worse concomitant and future axonal pathology.
- Higher GFAP was associated with future disability progression (Exp(B)=8.647, p=0.004).

Figure 1. Cross-sectional correlation matrix (heatmap) between follow-up proteomic data and follow-up diffusion tensor imaging outcomes in persons with multiple sclerosis.

Figure 2. Longitudinal correlation matrix (heatmap) between baseline proteomic data and follow-up diffusion tensor imaging outcomes in persons with multiple sclerosis.

Table 2. Linear step-wise regression determining associations between baseline proteomics and future microstructural DTI-based outcomes (at follow-up)

Legend: GFAP – glial fibrillary acidic protein, MOG - myelin oligodendrocyte glycoprotein, IL-12B – interleukin-12 subunit B, FLRT2 - fibronectin leucine rich transmembrane protein 2, TNFRSF10a - tumor necrotic factor receptor superfamily member 10a, NfL – neurofilament light chain, DTI – diffusion tensor imaging, MD – mean diffusivity, FA – fractional anisotropy, GM – gray matter, NABT – normal-appearing brain tissue, NAWM – normal-appearing white matter, LV – lesion volume.

Conclusion

- Multiple proteomic biomarkers are independently associated with greater severity of axonal brain pathology as measured by diffusion tensor imaging.
- Baseline serum GFAP levels can predict future disability progression.

Disclosures

- Dejan Jakimovski and Niels Bergsland have nothing to disclose.
 Ferhan Qureshi, Anisha Keshavan and Kelly Leyden are employees of Octave Bioscience. Victor Gehman was an employee of Octave Bioscience
- at the time the study was performed
 Murali Ramanathan received research funding from the National Multiple Sclerosis Society, Department of Defense and National Institute of Neurological Diseases and Stroke.
- Michael G. Dwyer received compensation from Keystone Heart for consultant fees. He received financial support for research activities from Bristol Myers Squibb, Mapi Pharma, Keystone Heart, Protembis and V-WAVE Medical.
- Bianca Weinstock-Guttman received honoraria for serving in advisory boards and educational programs from Biogen Idec, Novartis, Genentech, Genzyme and Sanofi, Janssen, Abbvie and Bayer. She also received support for research activities from the National Institutes of Health, National Multiple Sclerosis Society, Department of Defense, and Biogen Idec, Novartis, Genentech, Genzyme and Sanofi.
- Robert Zivadinov has received personal compensation from Bristol Myers Squibb, EMD Serono, Sanofi, Keystone Heart, Protembis and Novartis for speaking and consultant fees. He received financial support for research activities from Sanofi, Novartis, Bristol Myers Squibb, Octave, Mapi Pharma, Keystone Heart, Protembis and V-WAVE Medical.
